AMENDMENT NO.1 JANUARY 1987
TO
IS : 4995 (Part 1) - 1974 CRITERIA FOR DESIGN OF REINFORCED CONCRETE BINS FOR THE STORAGE OF GRANULAR AND POWDERY MATERIALS

PART 1 GENERAL REQUIREMENTS AND ASSESSMENT OF BIN LOADS
(First Revision)

(Page 10, clause 6.1.1.2) — Substitute the following for the existing formula:

\[ \sum_{0}^{z} P_w = \pi D W R \left[ z - z_{se} (1 - e^{-z/z_{se}}) \right] \]

(Page 12, clause 6.2.3, Note) — Add 'm/h' as unit under \( v_s \) in the informal table given in the Note.

(Page 13, Fig. 4) — Substitute the following for the existing figure:

![Diagram of pressure scheme during pneumatic emptying]

\( W_{min} = \) Minimum bulk density of the stored material.

**Fig. 4 Pressure Scheme During Pneumatic Emptying**

(Page 15, clause 6.3.3.3) — Substitute the following for the existing clause:

'6.3.3.3 Bins for storage of powdery materials are often equipped with devices for pneumatic emptying and when these devices are used for aeration of stored material, loosening of the material in the region of the outlet occurs. In this case, no significant increase in load due to the air supply has so far been detected.'
0. FOREWORD

0.1 This Indian Standard (Part I) (First Revision) was adopted by the Indian Standards Institution on 9 December 1974, after the draft finalized by the Criteria for Design of Structures Sectional Committee had been approved by the Civil Engineering Division Council.

0.2 Storage structures like bins (silos and bunkers) for storing different materials are one among the important structures coming up in any industrial or organized storage complex. The necessity to store and contain materials like coke, coal, ores in the various steel plants and other industrial establishments cannot be overemphasized. In cement factories as well as in construction projects, cement is stored in large silos. On the agricultural front the foodgrain storage structures play a vital role in ensuring the supply of foodgrains at all times of the year. Bulk storage of materials in bins has certain advantages over other forms of storage. Therefore, the necessity to formulate standard criteria for design of such structures has been felt and this standard is aimed at giving the necessary guidelines to arrive at the structural design of reinforced concrete bins for the storage of various materials of different properties and characteristics.

0.3 This standard published in 1968 covered the requirements of the structural design for foodgrain storage bins (silos). It has been felt that instead of bringing out one separate standard to cover the requirements of all materials other than foodgrains, it would be judicious to cover the subject under one standard in which provisions for bins storing different materials could be dealt with adequately. Therefore, the first revision of this standard had been taken up to cover the requirements of storage bins for all materials including foodgrains.
0.4 The different stored materials, such as coke, coal, ores, foodgrains, fertilizers, cement and flour can be classified either as granular or powdery materials. Extensive research work all over the world has indicated that assessment of bin loads caused due to a stored material would require different treatments depending upon whether it is a granular or powdery material. Considering this, the standard has now been brought out in two parts, namely, Part I — General requirements and assessment of bin loads, and Part II — Design criteria.

0.5 In the formulation of this standard due weightage has been given to the findings of recent research and international coordination amongst the standards and practices prevailing in different countries. This has been met with by referring to the following standards and publications:

0.5.1 In view of the continuing research done on flow characteristics of materials, the emphasis in the code is on structural adequacy of bins. However, as regards flow characteristics of the materials, the designers would be well advised to consult the relevant literature. This code is based on the latest available data and is amenable to review as and when more reliable information on this subject becomes available.

0.6 For the purpose of deciding whether a particular requirement of this standard is complied with, the final value, observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS: 2-1960*. The number of significant places retained in the rounded off value should be the same as that of the specified value in this standard.

1. SCOPE

1.1 This standard (Part I) deals with the general requirements and assessment of bin loads for granular and powdery materials.

1.2 This standard covers circular, polygonal and interstice bins.

1.3 This standard deals with the storage of materials in dry condition for which properties are given in Table 1. However, if moisture content, temperature, etc, vary, the actual values would have to be arrived at as indicated under Note of Table 1. Provisions for thermal insulations,

*Rules for rounding off numerical values (revised).
details of joints, weather proofing of joints, etc, are not covered in this standard.

2. TERMINOLOGY

2.0 For the purpose of this standard, the following definitions shall apply.

2.1 Aeration — A process in which air is moved through the stored material for ventilation.

2.2 Arching — A phenomenon in the bin during the emptying of a stored material giving rise to formation of arches of the material across the bin walls.

2.3 Bin — A storage structure, circular or polygonal in plan and intended for storing bulk materials in vertical direction. Silo is a bin circular or polygonal in plan. Bunker is a bin whose cross section in plan would be square or rectangular.

2.4 Bin Loads — Loads exerted by a stored material on the walls of a bin.

2.5 Foodgrain — All cereals, pulses, millets, except oil seeds.

2.6 Granular Materials — All materials having mean particle size more than 0.2 mm. No cohesion between the particles is assumed.

2.7 Interstice Bin — Bin that is formed out of the space enclosed by a battery of interconnected bins.

2.8 Powdery Materials — All materials having mean particle size less than 0.06 mm.

3. NOTATIONS

3.1 For the purpose of this standard, the following notations shall have the meaning indicated against each:

- $A$ = Horizontal interior cross-sectional area of bin.
- $a$ = Side of a square bin or shorter side of a rectangular bin.
- $b$ = Longer side of a rectangular bin.
- $D$ = Internal diameter of a circular bin.
- $d$ = Maximum diameter of the circle that can be inscribed in the bin.
- $h$ = Height of the bin.
- $P_a$ = Pressure of air injected for pneumatic emptying of a bin.
- $P_h$ = Horizontal pressure on bin walls due to stored material.
- $P_i$ = Stands for $P_h$ or $P_v$ or $P_w$ as the case may be.
**IS: 4995 (Part I) - 1974**

\[ P_{ht} = \text{Pressure obtained on the wall of a bin imagined to be enlarged in plan so as to make the eccentric opening concentric.} \]

\[ P_v = \text{Vertical pressure on the horizontal cross section of the stored material.} \]

\[ P_w = \text{Vertical load transferred to the wall due to friction between material stored and bin wall.} \]

\[ R = A/U. \]

\[ U = \text{Interior perimeter of the bin.} \]

\[ W = \text{Bulk density of stored material.} \]

\[ Z = \text{Depth below the levelled surface of the maximum possible fill in the bin (Fig. 1).} \]

\[ \phi = \text{Angle of internal friction of the stored material.} \]

\[ \delta = \text{Angle of wall friction.} \]

\[ \lambda = \text{Pressure ratio } (\lambda = P_h/P_v). \]

\[ \lambda_f = \text{Pressure ratio during filling.} \]

\[ \lambda_e = \text{Pressure ratio during emptying.} \]

\[ \mu = \text{Coefficient of wall friction } (\mu = \tan \delta). \]

\[ \mu_f = \text{Coefficient of wall friction during filling.} \]

\[ \mu_e = \text{Coefficient of wall friction during emptying.} \]

**Fig. 1 Depth Below the Levelled Surface of the Maximum Possible Fill in the Bin**

### 4. GENERAL

**4.1 Location** — Location of bins and specially those storing foodgrains shall conform to the relevant provisions of IS: 3453-1966* and IS: 5503 (Part I) -1969†.

*Code of practice for construction of hexagonal type of concrete-cum-masonry bins for bulk storage of foodgrains.

†General requirements for silos for grain storage: Part I Constructional requirements.
4.2 Economic Considerations — Dimensions, shape and layout of the bins, etc shall be so arrived as to effect optimum economies, the details of which are given in 4.2.1 to 4.2.3. In addition, the material handling facilities shall also be considered.

4.2.1 Dimensions — Volume of each bin and height to diameter ratio shall be governed by its storage and functional requirements of materials. To achieve a reduction in lateral pressure over a larger height, it may be preferable to select a height/diameter ratio greater than or equal to two.

4.2.2 Shape — A bin may be circular or polygonal in plan and is provided with a roof and bottom which may be flat, conical and pyramidal. In case of gravity flow bin, the angle made by the hopper with the horizontal, shall preferably be 15° more than the angle of repose of the stored material.

4.2.3 Layout — Storage bins may be either free standing individual bins or arranged in the form of batteries of free standing bins or bins interconnected in one or both the directions.

5. DESIGN PARAMETERS

5.0 Design parameters of stored materials include bulk density, angle of internal friction, angle of wall friction and pressure ratio (\( \lambda \)) which are the governing factors for the computation of bin loads. Storage and flow characteristics of granular materials differ widely from those of powdery materials.

5.1 Shape of the Bin — The cross-sectional shape of the bin is taken into account by the factor \( R = A/U \). In the case of interstice bins, the value of \( R \) shall be approximated by the value of \( R \) for an equivalent square bin of the same area.

5.2 Bulk Density and Angle of Internal Friction — Table 1 gives the values of bulk density and angle of internal friction for some of the commonly stored materials.

5.3 Wall Friction — In the absence of reliable experimental data, the angle of wall friction for granular and powdery materials, irrespective of the roughness of bin wall, may be taken as given in Table 2.

5.3.1 For materials having mean particle diameters in between 0·06 mm and 0·2 mm the necessary values of angle of wall friction may be obtained by linear interpolation. If there is a possibility that the effect of moisture, pressure increase due to consolidation, etc, may change the angle of wall friction, \( \delta \) to a value than that indicated in Table 2, then its value should preferably be determined experimentally.

5.3.2 Pressure Ratio — For the purpose of computing bin loads, the ratio of horizontal to vertical pressure, \( \lambda \), may be assumed as given in Table 2.

6. ASSESSMENT OF BIN LOADS

6.0 Bin Loads — There are three types of loads caused by a stored material in a bin as shown in Fig. 2. They are:

- a) horizontal load or horizontal pressure ($P_h$) acting on the side walls,
- b) vertical load or vertical pressure ($P_v$) acting on the cross-sectional area of the bin filling, and
- c) frictional wall load or frictional wall pressure ($P_w$) introduced into the side walls through wall friction.

![Fig. 2 Bin Loads](image.png)

6.0.1 In this standard Janssen’s theory has been used for the assessment of bin loads in which the value of $\lambda$, $\phi$, and $h'$ are assumed to be constant.
along the bin height. However, where necessary, the variation of $W$ and $\delta$ along the depth may be determined experimentally and used in the development-derivation of Janssen's theory for computation of bin loads. Designs can be carried out using mass/funnel flow characteristics, details for which are not at present covered in the scope, and designers are well advised to consult relevant literature.

6.1 Bin Loads due to Granular Materials

6.1.1 Normal Filling and Emptying

6.1.1.1 Maximum pressures — The maximum values of the horizontal pressures on the wall ($P_h$), the vertical pressure on the horizontal cross section of the stored material ($P_v$) and the vertical load transferred to the wall per unit area due to friction ($P_w$) shall be calculated as follows (see also Fig. 2):

<table>
<thead>
<tr>
<th>Name of Pressure</th>
<th>During Filling</th>
<th>During Emptying</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum $P_v$</td>
<td>WR</td>
<td>WR</td>
</tr>
<tr>
<td>Maximum $P_h$</td>
<td>(WR)</td>
<td>(WR)</td>
</tr>
<tr>
<td>Maximum $P_w$</td>
<td>(\frac{WR}{\mu_f})</td>
<td>(\frac{WR}{\mu_v})</td>
</tr>
</tbody>
</table>

6.1.1.2 $P_v$ and $P_w$ cannot be maximum at the same time. Hence for the design of hopper bottom, maximum $P_v$ (during filling) should be considered and this value will be the maximum $P_v$ at the particular depth multiplied by area of cross section of bin. The maximum $P_w$ (emptying) shall be calculated when the side walls are to be designed at a particular depth as:

\[
\sum_{0}^{Z} P_w = \pi DWR \left( Z + \frac{1}{Z_{oo}} e^{-Z/Z_{oo}} - Z_{oo} \right)
\]

If $h/D$ ratio is less than or equal to 2, the values shall be:

a) the total weight of stored material when hopper bottom is to be designed, and

b) the value indicated as $P_w$ when side walls are to be designed.

6.1.1.3 Variation of pressure along the depth — The variation of $P_v$, $P_h$ and $P_v$ along the depth of the bin may be obtained from the expression given below (Fig. 3):

\[
P_i (Z) = (P_i)_{max} (1 - e^{-Z/Z_0})
\]
where $P$ stands for pressure and suffix $i$ stands for $w$, $h$ or $v$ corresponding to the pressures $P_w$, $P_h$ or $P_v$ respectively and $Z_o$ assumes the values given below:

- **During filling**, $Z_{of} = R/\mu_i \lambda_i$
- **During emptying**, $Z_{oe} = R/\mu_e \lambda_o$

Appendix A gives the values of $(1-e^{-Z/Z_o})$ for different values of $Z/Z_o$. Intermediate values may be obtained with sufficient accuracy by linear interpolation.

---

**Fig. 3 Pressure Variation Along Bin Depth**

**6.1.1.4 Governing loading cases** — In general, the loading cases as indicated in Table 3 will give the governing design pressures.

<table>
<thead>
<tr>
<th>TABLE 3 GOVERNING LOADING CASES</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PRESSURE</strong></td>
</tr>
<tr>
<td>(1) $P_w$</td>
</tr>
<tr>
<td>(2) $P_h$</td>
</tr>
<tr>
<td>(3) $P_v$</td>
</tr>
</tbody>
</table>
6.2 Bin Loads due to Powdery Materials

6.2.1 Normal Filling and Emptying — Maximum design pressures under this case shall be computed as specified under 6.1. Appropriate values of various design parameters shall be taken from Tables 1 and 2.

6.2.2 Homogenization — In the case of homogenizing bin, the filling consists of powdery materials which is circulated by compressed air for mixing purposes. During homogenization of powdery materials the lateral and vertical pressures depend upon the volume of the empty space available in the upper portion of the bin. This may be kept about 40 percent of the total volume of the bin. The lateral and vertical pressures shall be calculated using the following expression and should not be less than pressure evaluated as in 6.1.1:

\[ P_h = P_v = 0.6 W \cdot Z \]

6.2.3 Rapid Filling — During rapid filling — material being filled at a rate higher than the minimum filling speed — up to a certain height \( Z_n \) from the top layer, the upper stored material flows like a fluid. The following expression may be used for computing the governing lateral pressures during rapid filling of a silo with a filling speed \( v \):

\[ \text{Rapid filling} \ (P_h) = 0.8 W \cdot Z_n \]

where

\[ Z_n = (v - v_o) \cdot t; \]
\[ v = \text{actual filling speed, m/h}; \]
\[ v_o = \text{the minimum filling speed, m/h}; \] and
\[ t = \text{time lapse of one hour}. \]

Note — The values of \( v_o \) shall be taken as follows:

<table>
<thead>
<tr>
<th>Material</th>
<th>( v_o )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cement</td>
<td>2.6</td>
</tr>
<tr>
<td>Pulverized lime</td>
<td>1.4</td>
</tr>
<tr>
<td>Wheat flour</td>
<td>4.8</td>
</tr>
</tbody>
</table>

6.2.3.1 Application of the formula given in 6.2.3 is only for materials filled at a rate more than the minimum filling speed for different materials. For speeds lesser than the minimum filling speed, the pressures in 6.1 shall apply. However, when the filling speed exceeds the minimum filling speed, a check should be made for the maximum pressure due to rapid filling from the greater values arrived at according to the formula given in 6.2.3 and the values given in 6.2.1, 6.2.2, 6.2.4 and 6.3.

6.2.4 Pneumatic Emptying — During pneumatic emptying air under pressure is blown inside the bin through a number of small holes located in the bin walls near the bin bottom. This causes liquefaction of the material in
the lower portion of the bin and gives rise to higher values of \( P_h \) and \( P_p \) (both being equal). The lateral pressures during pneumatic emptying shall be calculated as shown in Fig. 4.

**Fig. 4 Pressure Scheme for Pneumatic Emptying**

### 6.3 Effects Causing Increase in Bin Loads

**6.3.1 Eccentric Emptying** — Eccentric emptying of a bin gives rise to increased horizontal loads non-uniformly distributed over the periphery and extending over the full height of the bin. Eccentric outlets in bins shall be avoided as far as possible, and, where they have to be provided to meet functional requirements, due consideration shall be given in design to the increased pressure experienced by the walls. Till more information is available, the increased pressure may be calculated as given under 6.3.1.1. This increased pressure shall be considered, for the purpose of design, to be acting both on the wall nearer to the outlet as well as on the wall on the opposite side.

**6.3.1.1** The additional pressure \( P'_h \) shall be considered to act for the full height of the bin and is obtained from the expression given below:

\[
P'_h = P_{hi} - P_h
\]

where

- \( P_{hi} \) = pressure obtained on the wall of the bin imagined to be enlarged in plan so as to make the eccentric opening concentric, and
- \( P_h \) = horizontal pressure on the wall due to stored material.

\( P_{hi} \) and \( P_h \) shall be obtained as per 6.1.1.
6.3.1.2 The enlarged shape of the bin which is required for the purpose of computation of the pressure $P_{ha}$ shall be obtained as shown in Fig. 5.
6.3.1.3 The effect of eccentric outlets may be ignored in design if the eccentricity is less than \(d/6\) or the height of the bin is not greater than \(2d\), where \(d\) is the maximum possible diameter of the circle that can be inscribed in the bin.

6.3.2 Arching of Stored Material — Some stored materials are susceptible to arching action across the bin walls. The frequent collapse of such arches gives rise to increased vertical pressures. The vertical pressure on the bottom of the bin storing such materials shall be taken as twice the filling pressure, \(P_v\); however the load need not be assumed to be greater than \(W_z\).

6.3.3 Aeration of Stored Material — When bins are provided with equipment for ventilating the bin filling at rest, a distinction must be made between bins for granular material and bins for powdery material.

6.3.3.1 When the material is granular, an increase in the horizontal pressures is to be expected. Therefore, the horizontal pressure \(P_h\), as calculated as per 6.1.1.1, for filling, are to be increased by the inlet pressure of the air over that portion of the height of the bin in which the air inlets are located. From the level of the highest inlet upwards, this increase in pressure may be tapered off uniformly down to zero at the top of the bin.

6.3.3.2 For powdery materials the measurements made so far do not indicate any significant increases in load when ventilating.

6.3.3.3 Bins for storage of powdery materials are often equipped with devices for pneumatic emptying, and these bring about a loosening of the bin filling in the region of the outlet. In this case also, no significant increases in load due to the air supply have so far been detected.

6.3.4 Discharge Promoting Devices — Modern bins storing various materials may be provided with various discharge promoting devices such as inserts, bridge like structure above the outlet or relief nose. In all such cases the effective cross section of the bin is locally reduced. Recent research has given an indication that in such bins the horizontal wall pressures are excessively increased locally or along the entire bin height. In the absence of reliable knowledge available on the subject the designer is cautioned to assess the wall loads for such bins most judiciously and by carrying out experimental investigation.

6.4 Effects Causing Decrease in Bin Loads — In view of the load reducing effect of the bin bottom, the horizontal pressure during emptying may be reduced up to a height \(1.2d\) or \(0.75h\) whichever is smaller from the bin bottom. This may be considered as varying linearly from the emptying pressure at this height to the filling pressure at the bin bottom (see also Fig. 3).
